

# Chapter 3 I

## Cryptography And Network Security

---

# Objective

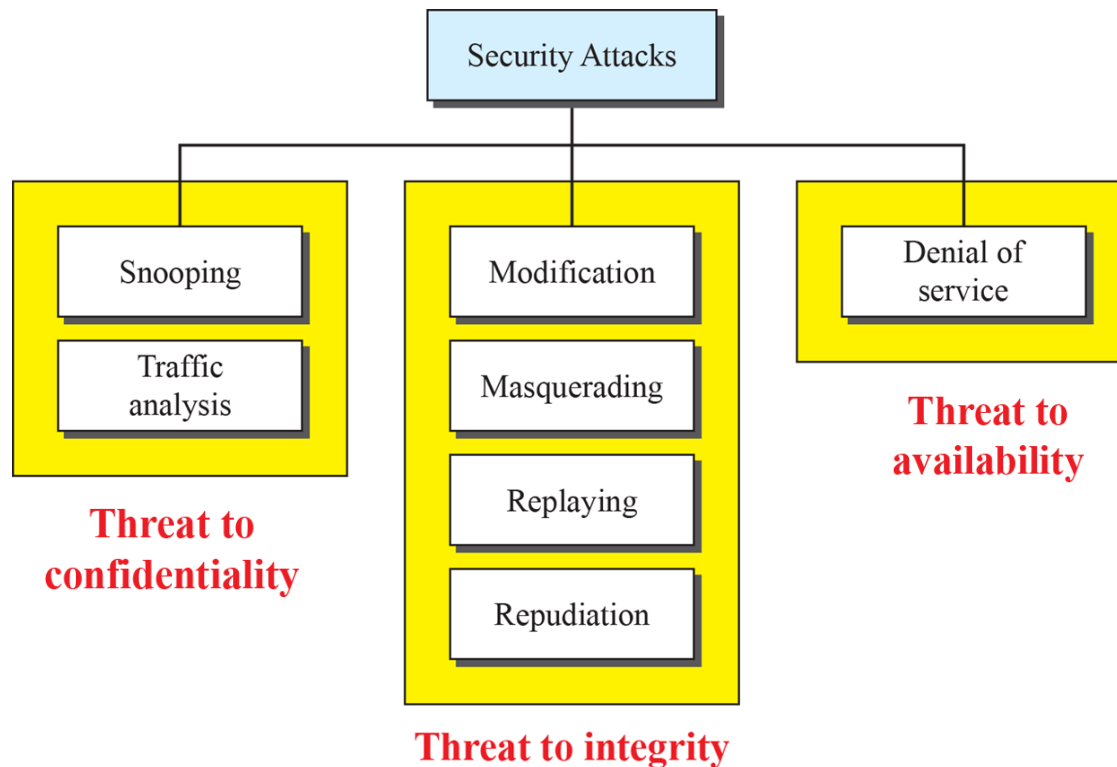

- Confidentiality, integrity, and availability
  - confidentiality is threatened by attacks such as snooping and traffic analysis.
  - how integrity is threatened by attacks such as modification, masquerading, replaying, and repudiation.
  - one attack that threatens availability, denial of service.
- Cryptography and Steganography

# Introduction

- Let us first discuss three security goals: **confidentiality, integrity, and availability.**
- To be secured, information needs to be hidden from unauthorized access – **confidentiality.**
- Protected from unauthorized change – **integrity.**
- Available to an authorized entity when it is needed - **availability.**

# Attacks

- Our three goals of security, confidentiality, integrity, and availability, can be threatened by security attacks.

*Taxonomy of attacks with relation to security goals*

# Services and Techniques

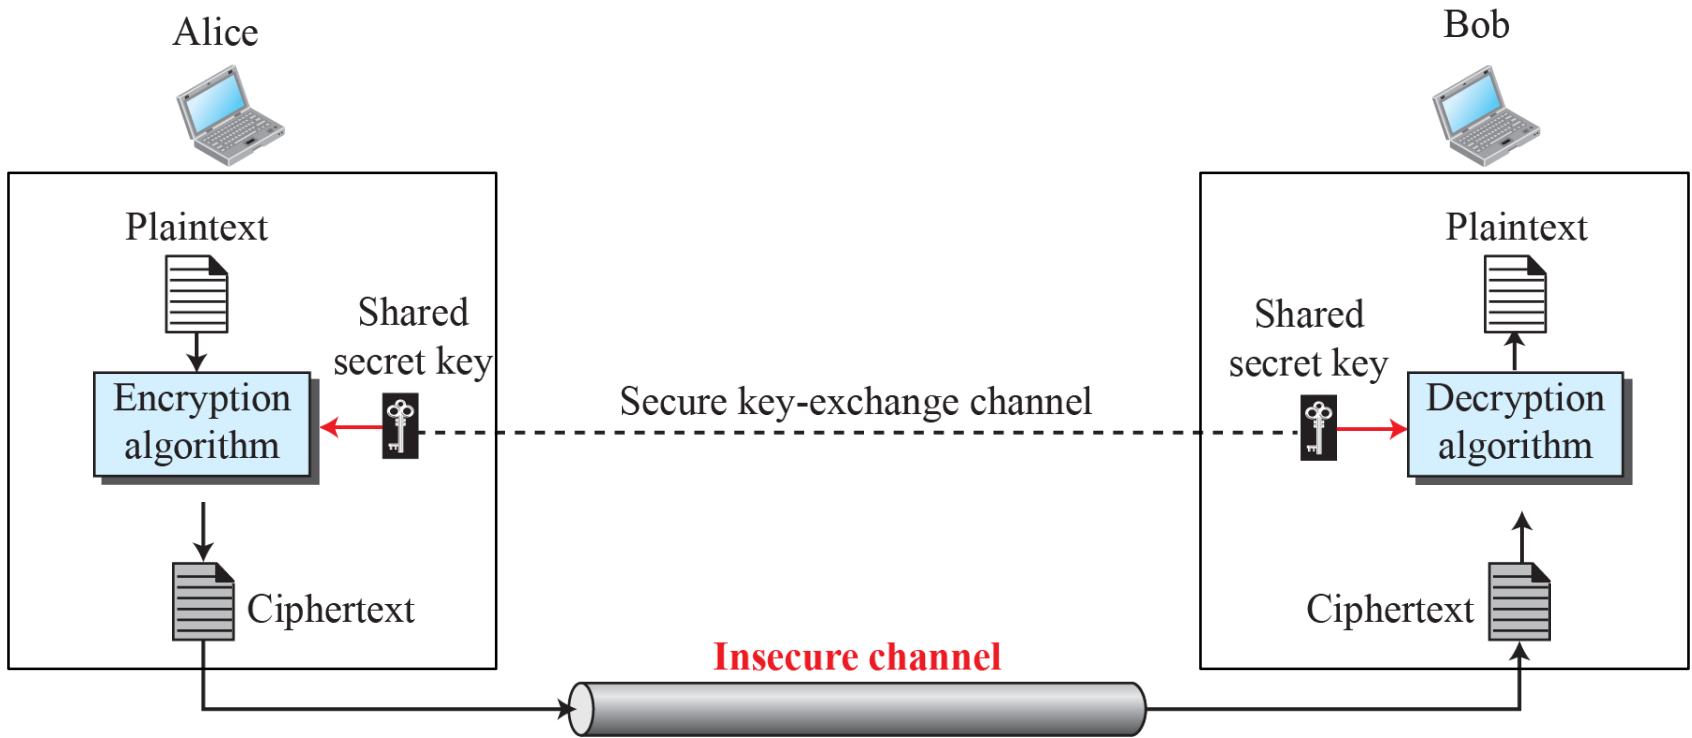

---

- ITU-T defines some security services to achieve security goals and prevent attacks.
- Two techniques are prevalent today: one is very general (**cryptology**) and one is specific (**steganography**).

# Confidentiality

- Confidentiality can be achieved using ciphers.
- Ciphers can be divided into two broad categories: symmetric-key and asymmetric-key.
- A symmetric-key cipher uses the same key for both encryption and decryption, and the key can be used for bidirectional communication, which is why it is called symmetric.

# Symmetric-Key Ciphers

*Symmetric-key encipherment as locking and unlocking with the same key*

Plaintext →	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
Ciphertext →	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W	X	Y	Z
Value →	00	01	02	03	04	05	06	07	08	09	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25

*Representation of plaintext and ciphertext characters in modulo 26*

# Example

- Use the additive cipher with key = 15 to encrypt the message “hello”.

## Solution

We apply the encryption algorithm to the plaintext, character by character:

Plaintext: h $\rightarrow$ 07	Encryption: $(07 + 15) \bmod 26$	Ciphertext: 22 $\rightarrow$ W
Plaintext: e $\rightarrow$ 04	Encryption: $(04 + 15) \bmod 26$	Ciphertext: 19 $\rightarrow$ T
Plaintext: l $\rightarrow$ 11	Encryption: $(11 + 15) \bmod 26$	Ciphertext: 00 $\rightarrow$ A
Plaintext: l $\rightarrow$ 11	Encryption: $(11 + 15) \bmod 26$	Ciphertext: 00 $\rightarrow$ A
Plaintext: o $\rightarrow$ 14	Encryption: $(14 + 15) \bmod 26$	Ciphertext: 03 $\rightarrow$ D

The result is “WTAAD”. Note that the cipher is monoalphabetic because two instances of the same plaintext character (*l*) are encrypted as the same character (*A*).

# Example

- Use the additive cipher with key = 15 to decrypt the message “WTAAD”.

## Solution

We apply the decryption algorithm to the plaintext character by character:

Ciphertext: W → 22	Decryption: $(22 - 15) \bmod 26$	Plaintext: 07 → h
Ciphertext: T → 19	Decryption: $(19 - 15) \bmod 26$	Plaintext: 04 → e
Ciphertext: A → 00	Decryption: $(00 - 15) \bmod 26$	Plaintext: 11 → l
Ciphertext: A → 00	Decryption: $(00 - 15) \bmod 26$	Plaintext: 11 → l
Ciphertext: D → 03	Decryption: $(03 - 15) \bmod 26$	Plaintext: 14 → o

The result is “hello”. Note that the operation is in modulo 26, which means that we need to add 26 to a negative result (for example  $-15$  becomes 11).

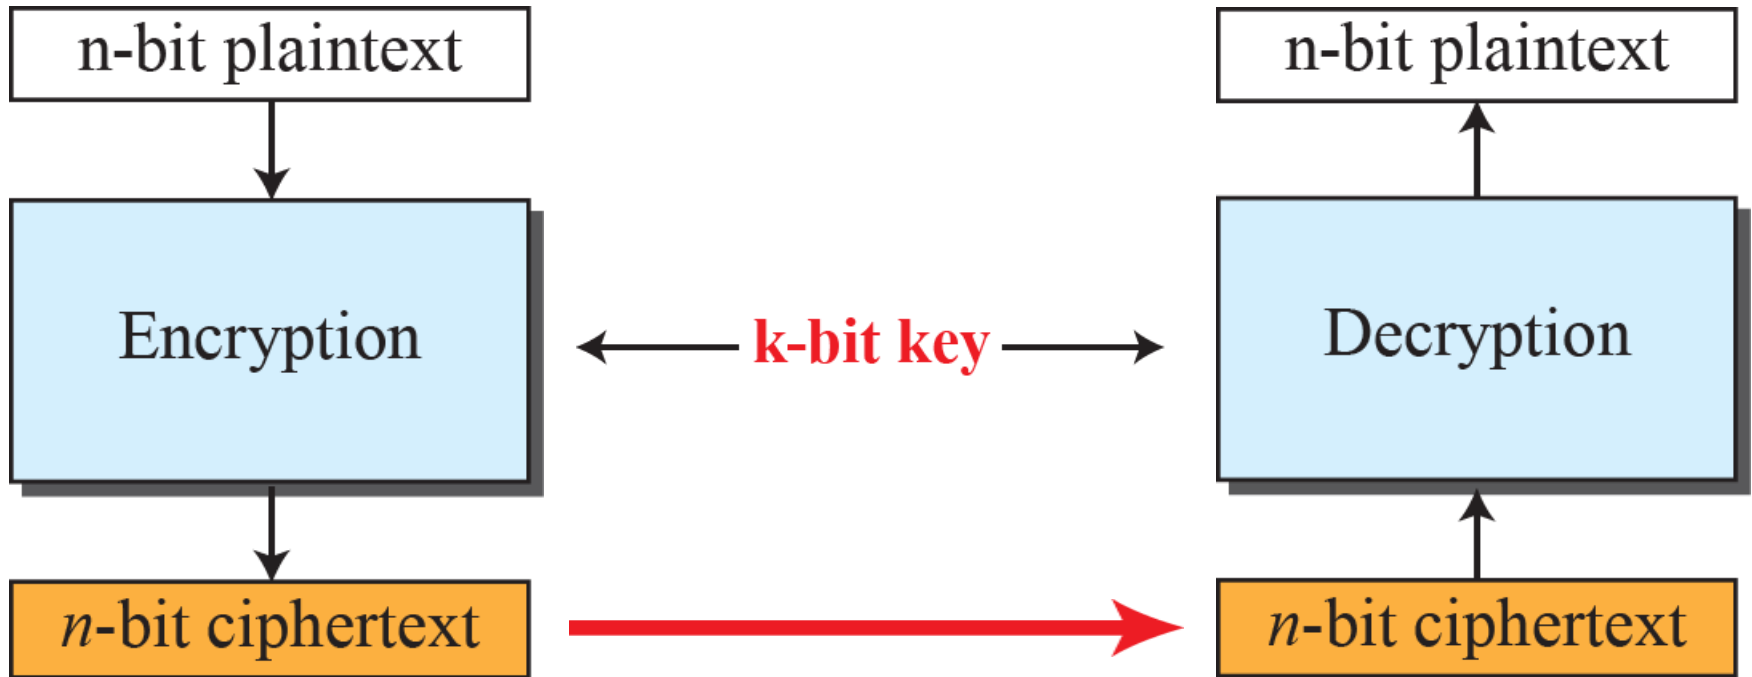

# Example

*An example key for a monoalphabetic substitution cipher*

Plaintext	→	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o	p	q	r	s	t	u	v	w	x	y	z
Ciphertext	→	N	O	A	T	R	B	E	C	F	U	X	D	Q	G	Y	L	K	H	V	I	J	M	P	Z	S	W

- We can use the key in to encrypt the message

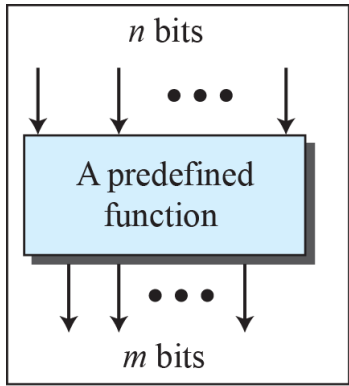

<b>Plaintext:</b>	this message is easy to encrypt but hard to find the key
<b>Ciphertext:</b>	ICFVQRVVNERFVRNVSIIYRGAHSLIOJICNHTIYBFGTICRXRS

*A modern block cipher*

Transposition

Substitution

Exclusive-OR

Shift

Swap

Split

Combine

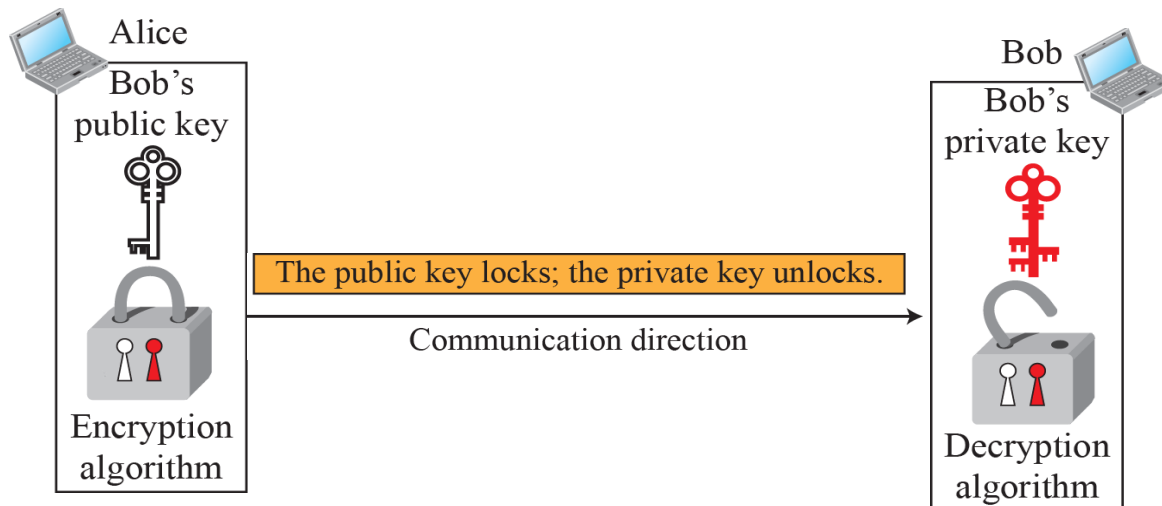

***Components of a modern block cipher***

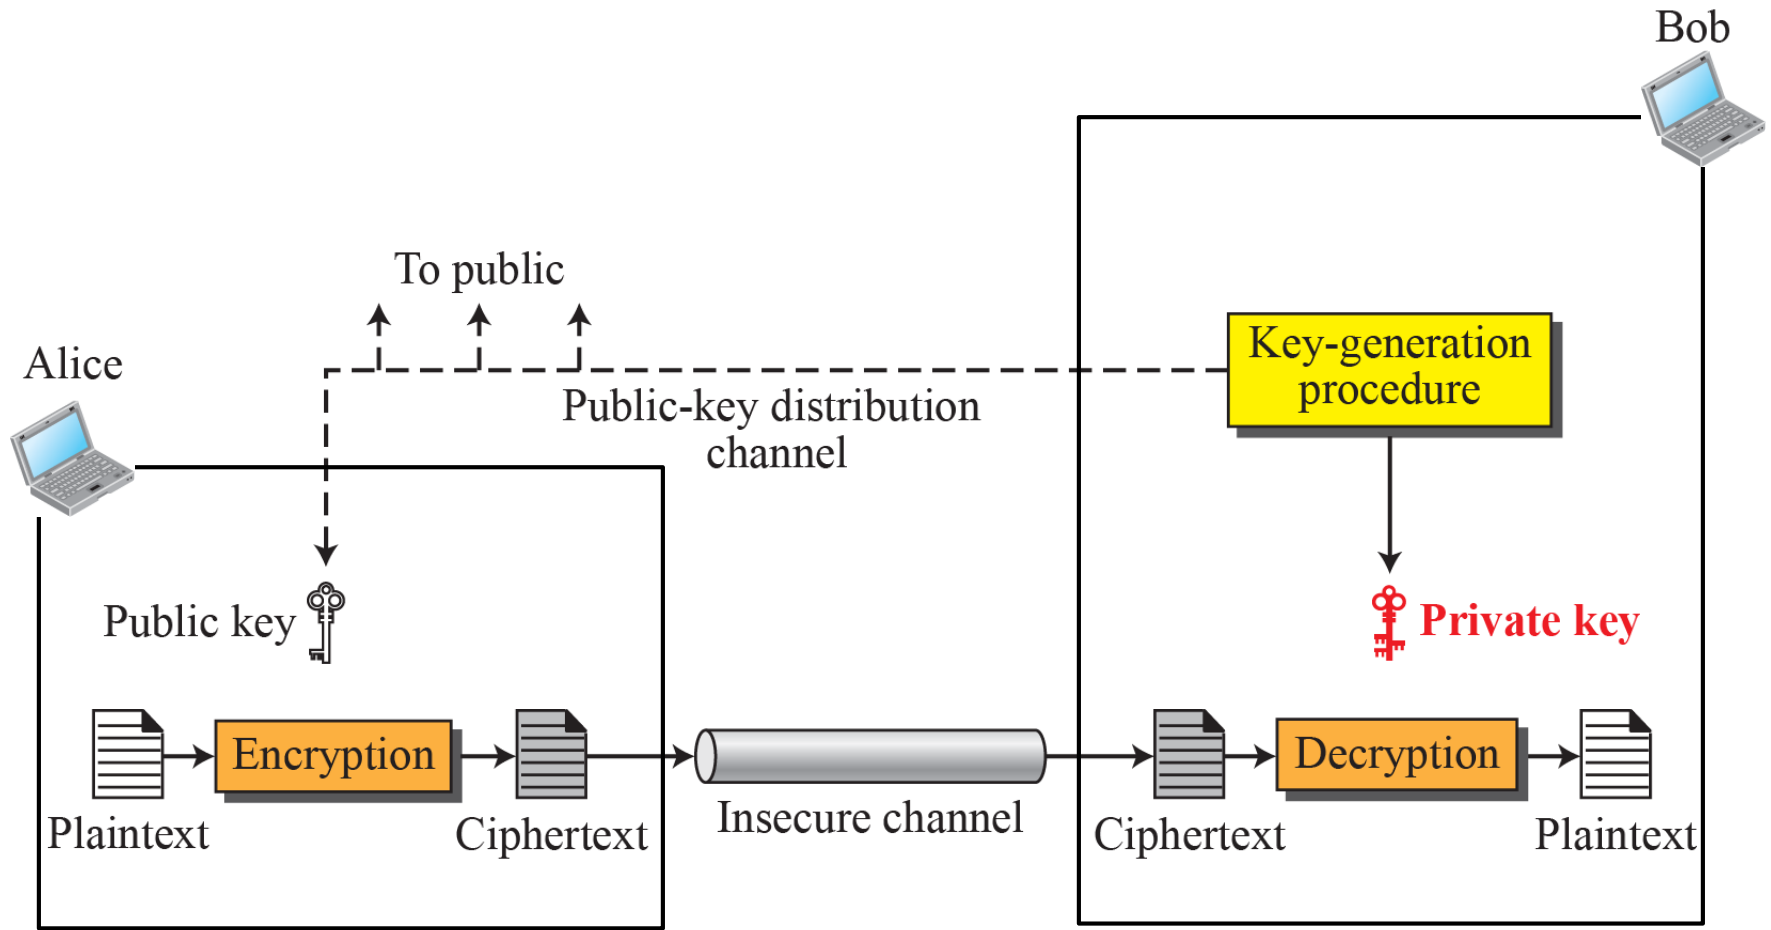

*Transposition cipher*

# Asymmetric-Key Ciphers

- Symmetric- and asymmetric-key ciphers will exist in parallel and continue to serve the community.
- We actually believe that they are complements of each other; the advantages of one can compensate for the disadvantages of the other.

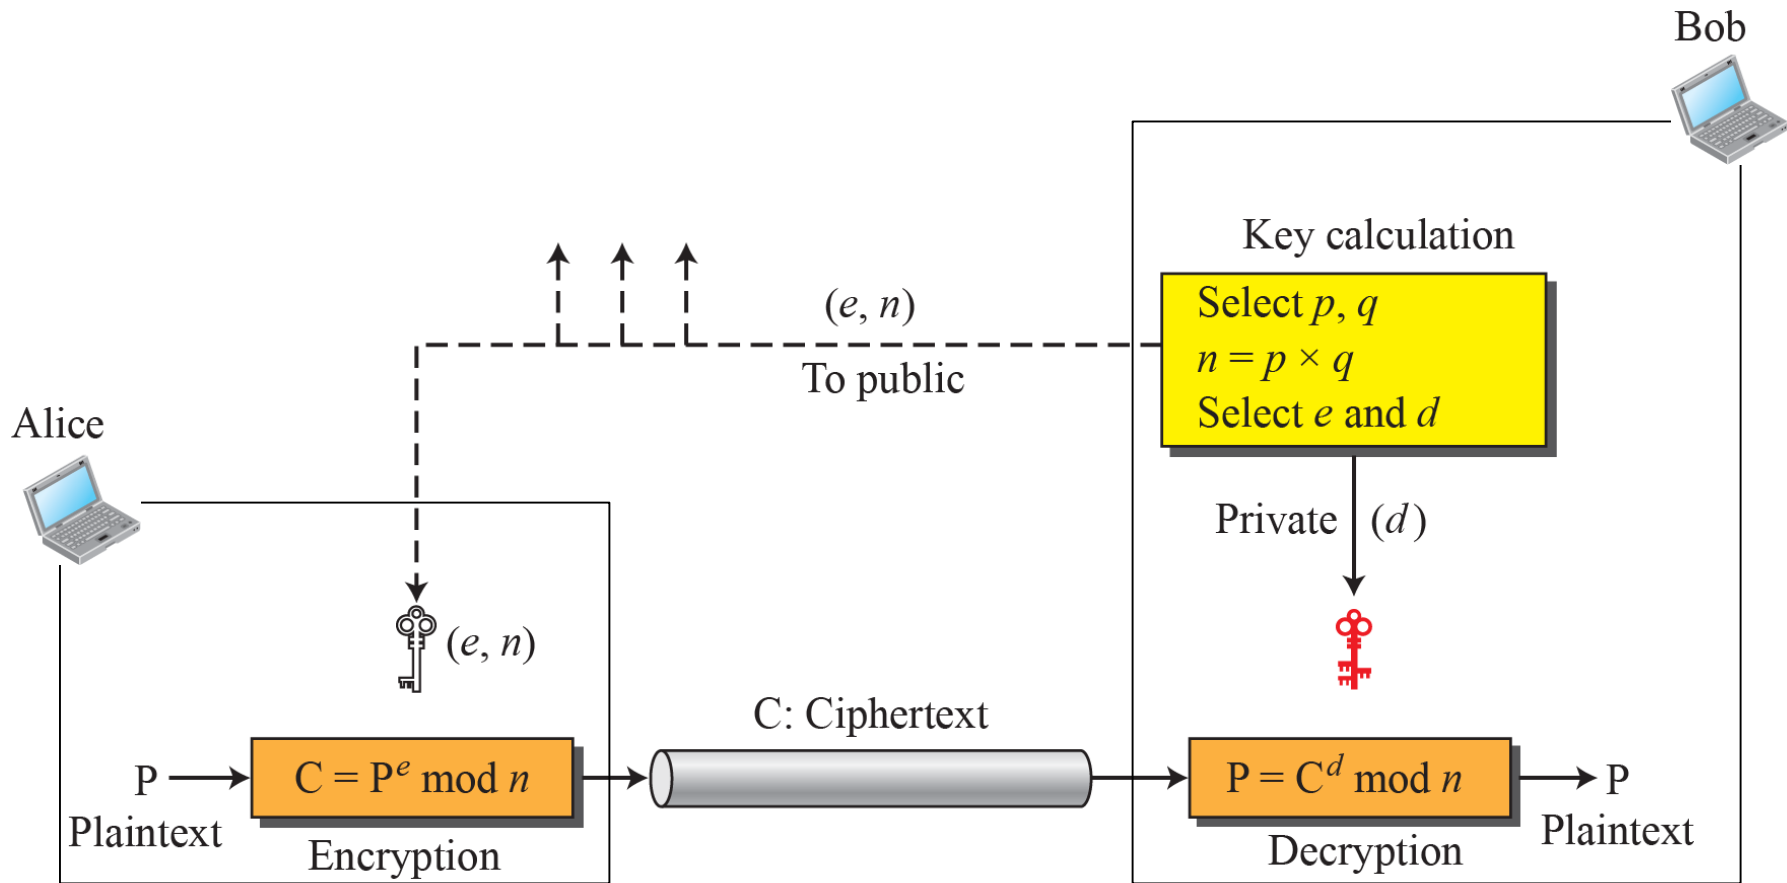

*Locking and unlocking in asymmetric-key cryptosystem*

*General idea of asymmetric-key cryptosystem*

***Encryption, decryption, and key generation in RSA***

# Example

- Let Bob choose 7 and 11 as  $p$  and  $q$  and calculate  $n = 7 \times 11 = 77$ ,  $\phi(n) = (7 - 1)(11 - 1)$ , or 60.
- If he chooses  $e$  to be 13, then  $d$  is 37. Note that  $e \times d \bmod 60 = 31$ . Now imagine that Alice wants to send the plaintext 5 to Bob.
- She uses the public exponent 13 to encrypt 5. This system is not safe because  $p$  and  $q$  are small.

Plaintext: 5

$$C = 5^{13} = 26 \bmod 77$$

Ciphertext: 26

Ciphertext: 26

$$P = 26^{37} = 5 \bmod 77$$

Plaintext: 5

# Realistic Example

- We choose a 512-bit  $p$  and  $q$ , calculate  $n$  and  $\phi(n)$ .
- We then choose  $e$  and calculate  $d$ . Finally, we show the results of encryption and decryption. The integer  $p$  is a 159-digit number.

$p =$	9613034531358350457419158128061542790930984559499621582258315087964 7940455056470638491257160180347503120986666064924201918087806674210 96063354219926661209
-------	--

# Example(continued)

The integer  $q$  is a 160-digit number.

$q =$	1206019195723144691827679420445089600155592505463703393606179832173 1482148483764659215389453209175225273226830107120695604602513887145 524969000359660045617
-------	---

The modulus  $n = p \times q$ . It has 309 digits.

$n =$	1159350417396761496889250986461588752377145737545414477548552613761 4788540832635081727687881596832516846884930062548576411125016241455 2339182927162507656772727460097082714127730434960500556347274566628 0600999240371029914244722922157727985317270338393813346926841373276 22000966676671831831088373420823444370953
-------	---

$\phi(n) = (p - 1)(q - 1)$  has 309 digits.

$\phi(n) =$	1159350417396761496889250986461588752377145737545414477548552613761 4788540832635081727687881596832516846884930062548576411125016241455 2339182927162507656751054233608492916752034482627988117554787657013 9234444057169895817281960982263610754672118646121713591073586406140 08885170265377277264467341066243857664128
-------------	---

# Example(continued)

Bob chooses  $e = 35535$  (the ideal is 65537). He then finds  $d$ .

$e =$	35535
$d =$	5800830286003776393609366128967791759466906208965096218042286611138 0593852822358731706286910030021710859044338402170729869087600611530 6202524959884448047568240966247081485817130463240644077704833134010 8509473852956450719367740611973265574242372176176746207763716420760 033708533328853214470885955136670294831

Alice wants to send the message “THIS IS A TEST”, which can be changed to a numeric value using the 00–26 encoding scheme (26 is the *space* character).

$P =$	1907081826081826002619041819
-------	------------------------------

# Example(continued)

The ciphertext calculated by Alice is  $C = P^e$ , which is shown below.

<b>C =</b>	4753091236462268272063655506105451809423717960704917165232392430544 5296061319932856661784341835911415119741125200568297979457173603610 1278218847892741566090480023507190715277185914975188465888632101148 3541033616578984679683867637337657774656250792805211481418440481418 4430812773059004692874248559166462108656
------------	--

Bob can recover the plaintext from the ciphertext using  $P = C^d$ , which is shown below.

<b>P =</b>	1907081826081826002619041819
------------	------------------------------

The recovered plaintext is “THIS IS A TEST” after decoding.

# Other Aspects of Security

---

- The cryptography systems that we have studied so far provide confidentiality.
- However, in modern communication, we need to take care of other aspects of security, such as integrity, message and entity authentication, nonrepudiation, and key management.

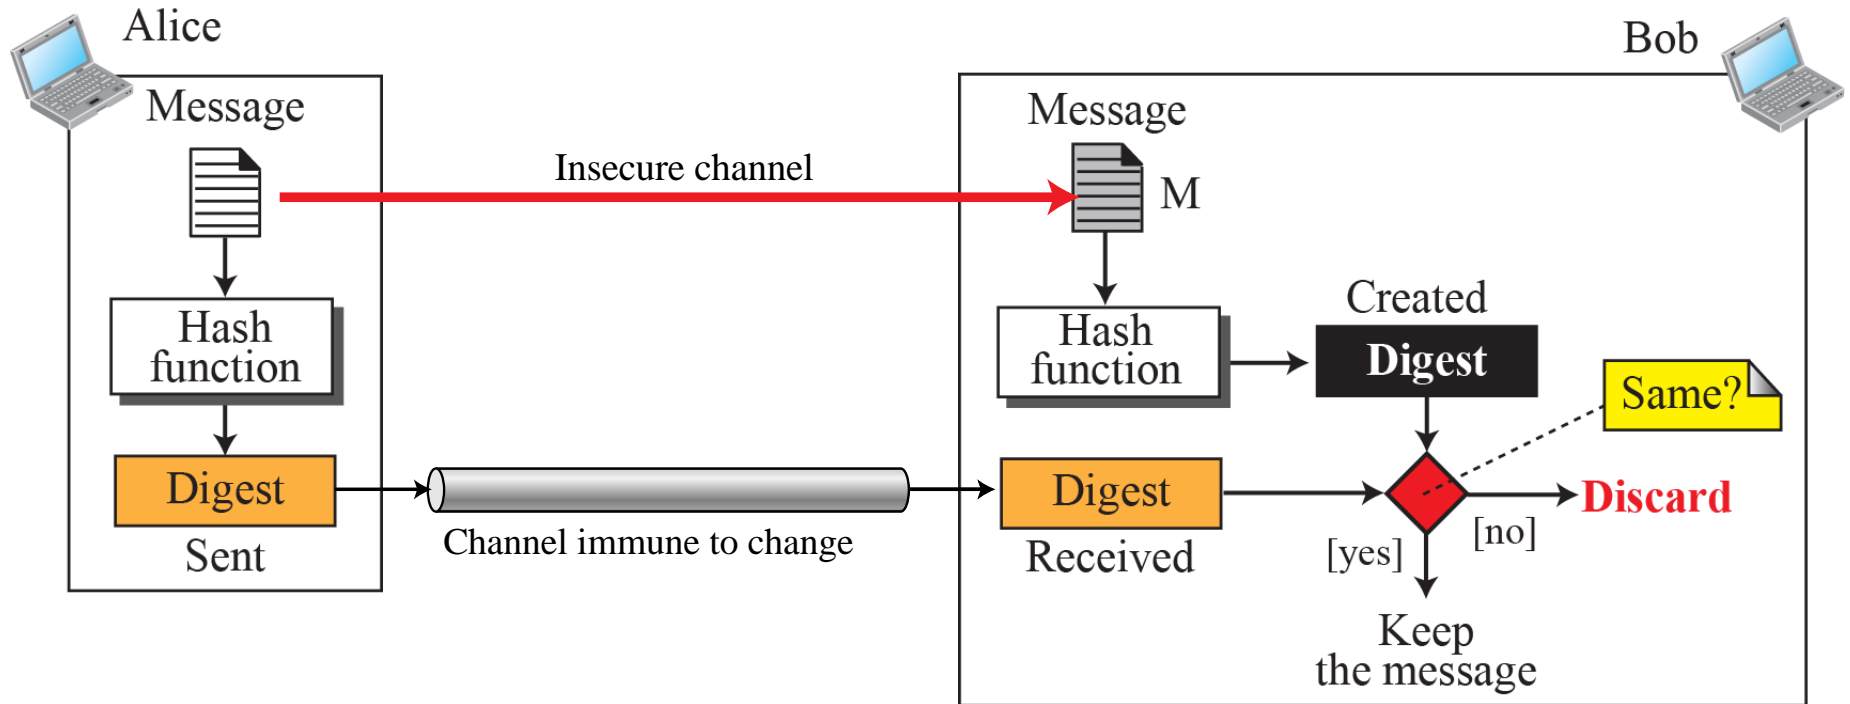

# Message Integrity

---

- There are occasions where we may not even need secrecy but instead must have integrity: the message should remain unchanged.
- For example, Alice may write a will to distribute her estate upon her death. The will does not need to be encrypted. After her death, anyone can examine the will.
- The integrity of the will, however, needs to be preserved. Alice does not want the contents of the will to be changed.

# Message digest

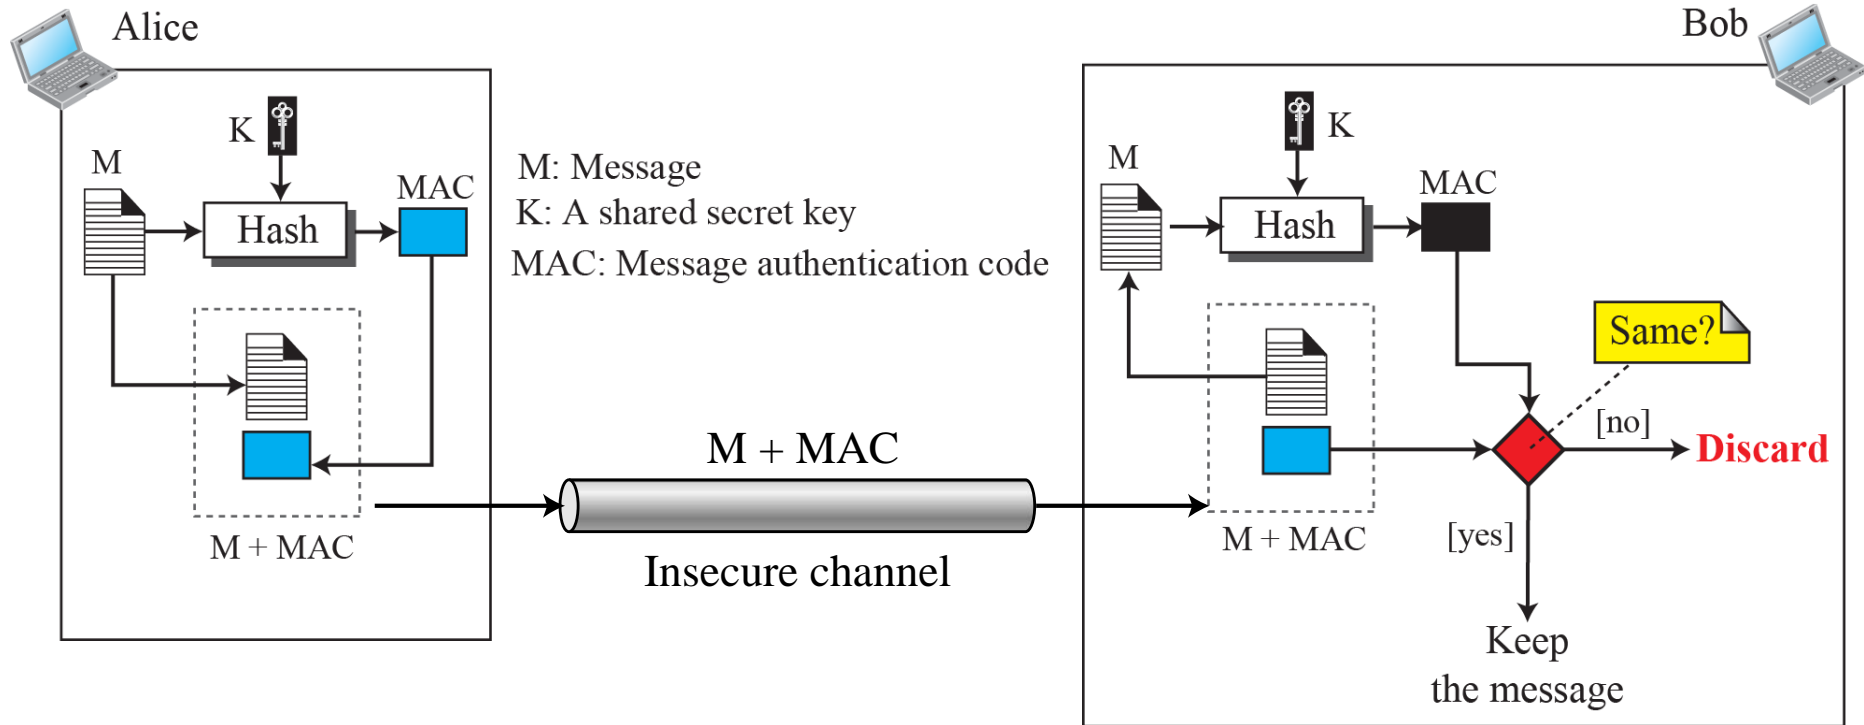

*Message and digest*

# Message Authentication

- A digest can be used to check the integrity of a message - that the message has not been changed.
- To ensure the integrity of the message and the data origin authentication - that Alice, not somebody else, is the originator of the message - we need to include a secret shared by Alice and Bob (that Eve does not possess) in the process.
- We need to create a message authentication code (MAC).

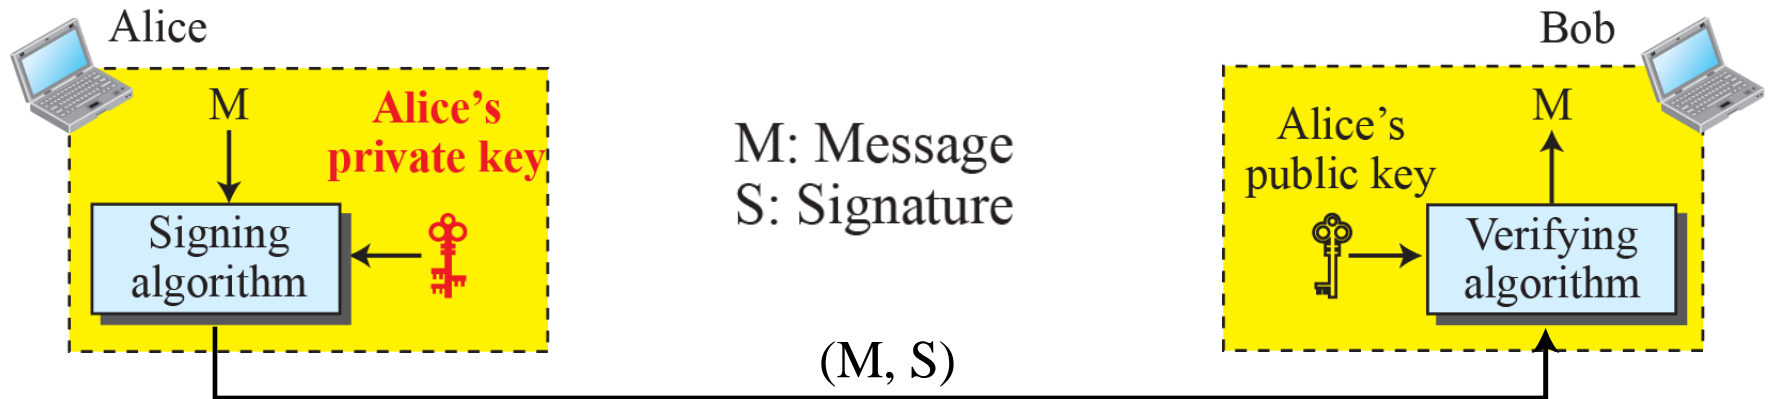

# MAC

*Message authentication code*

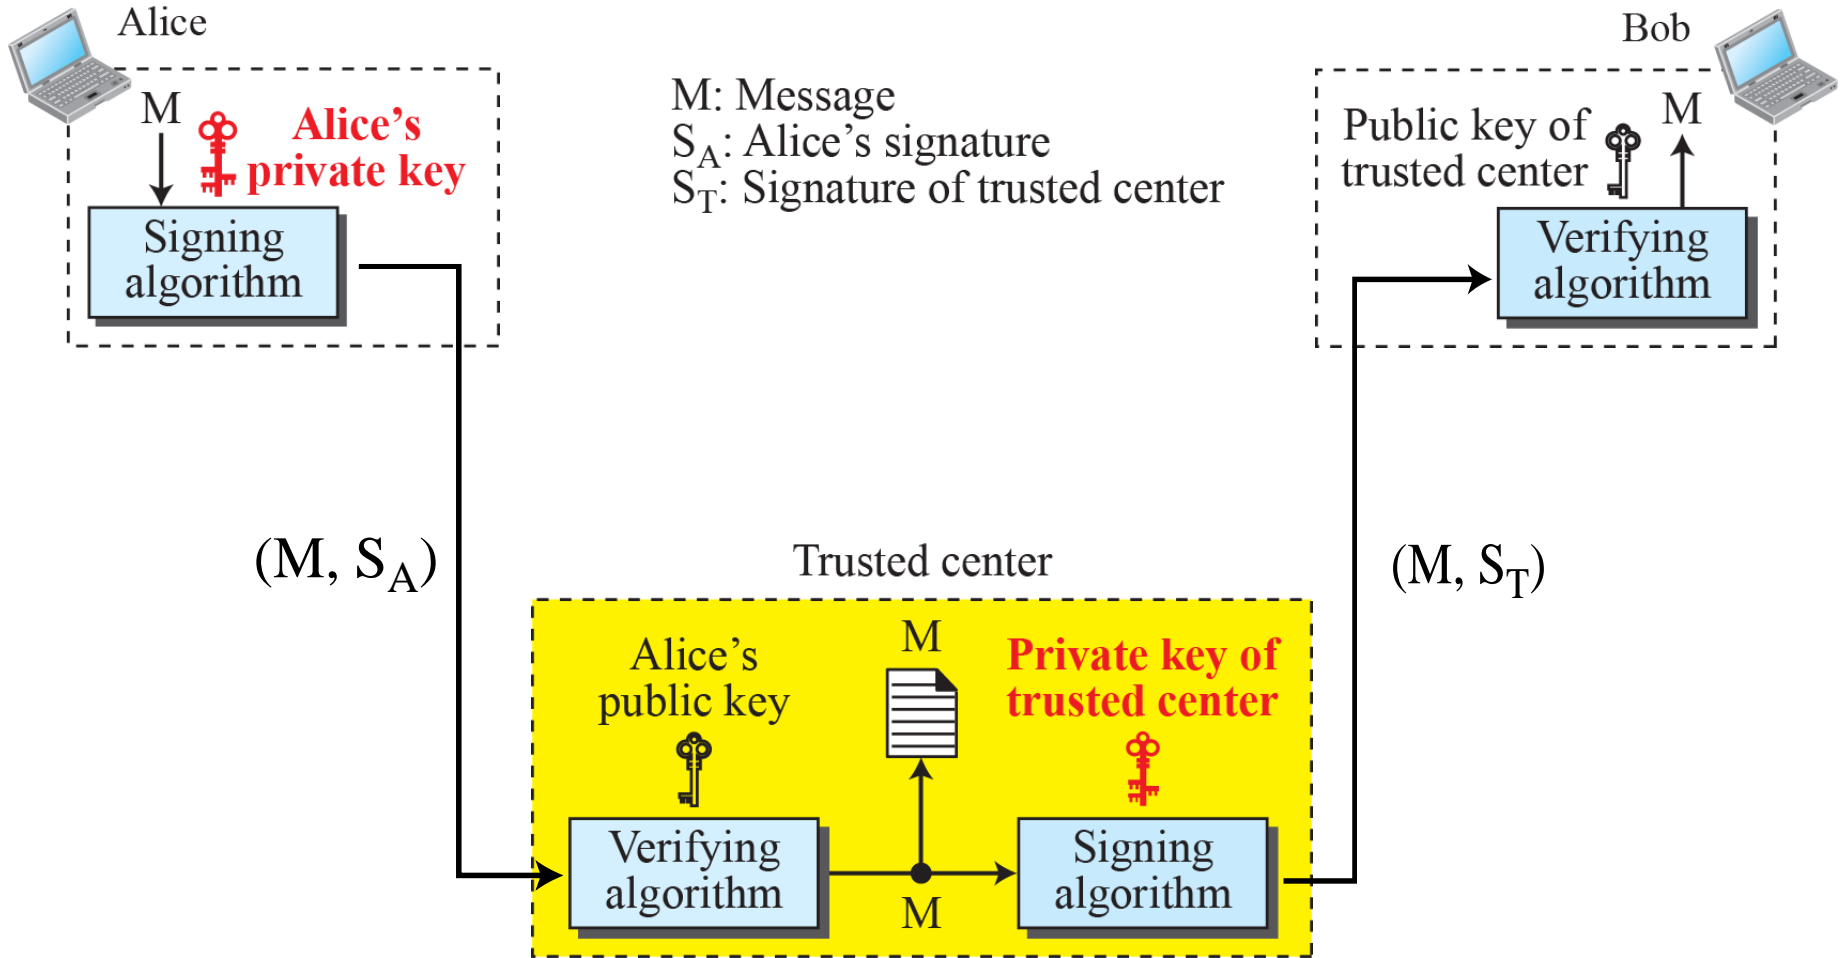

# Digital Signature

- Another way to provide message integrity and message authentication is a digital signature.
- A MAC uses a secret key to protect the digest; a digital signature uses a pair of private-public keys.

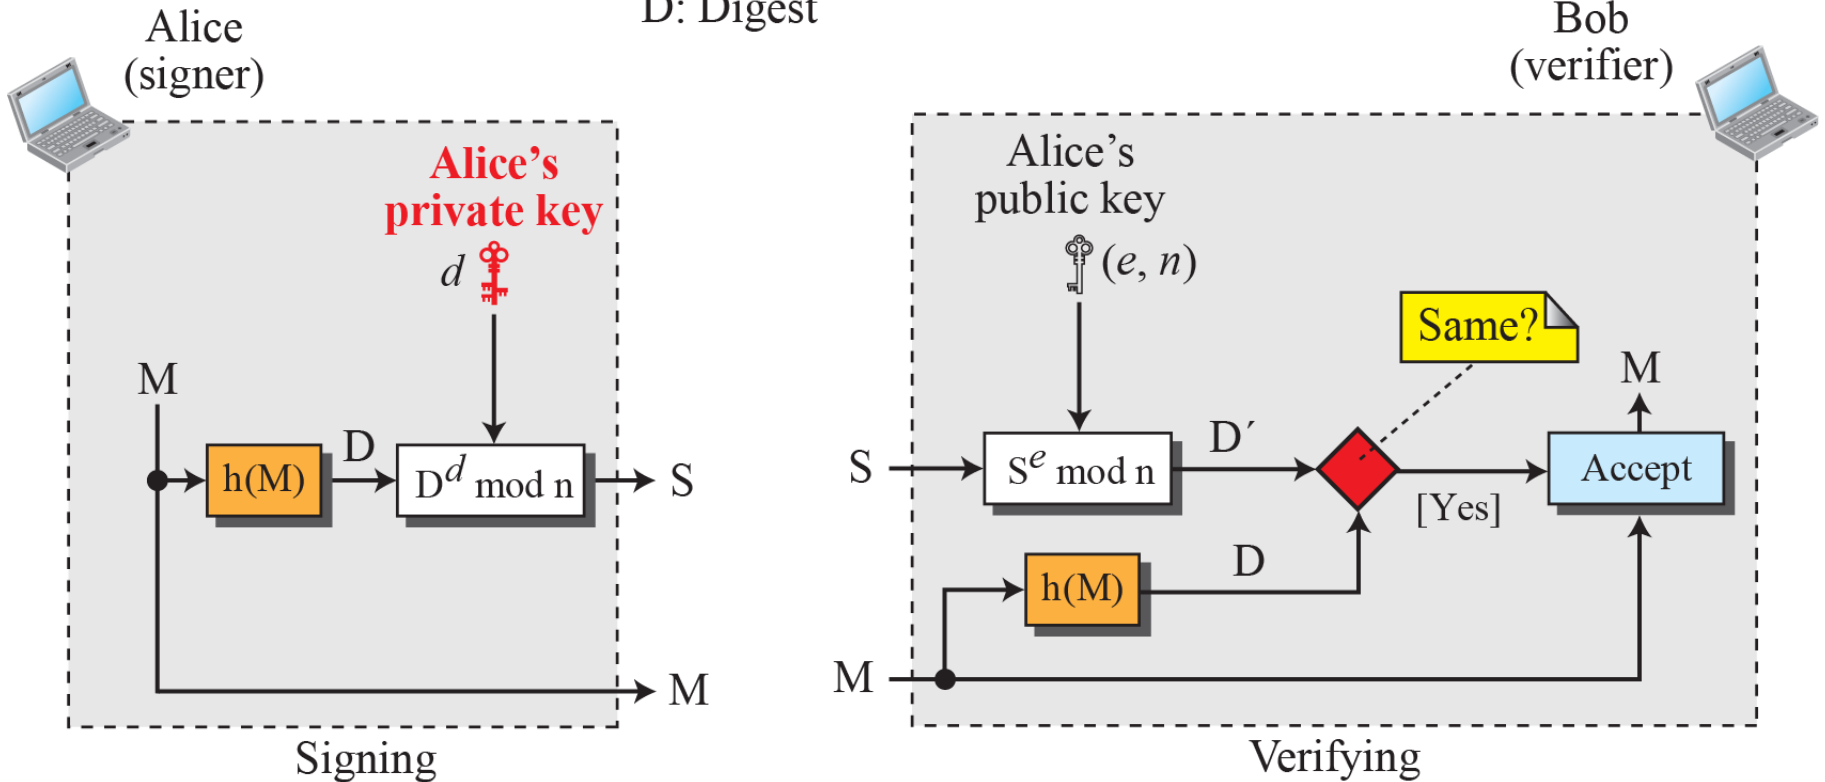

*Digital signature process*

# Non-repudiation

*Using a trusted center for non-repudiation*

M: Message  
S: Signature  
D: Digest

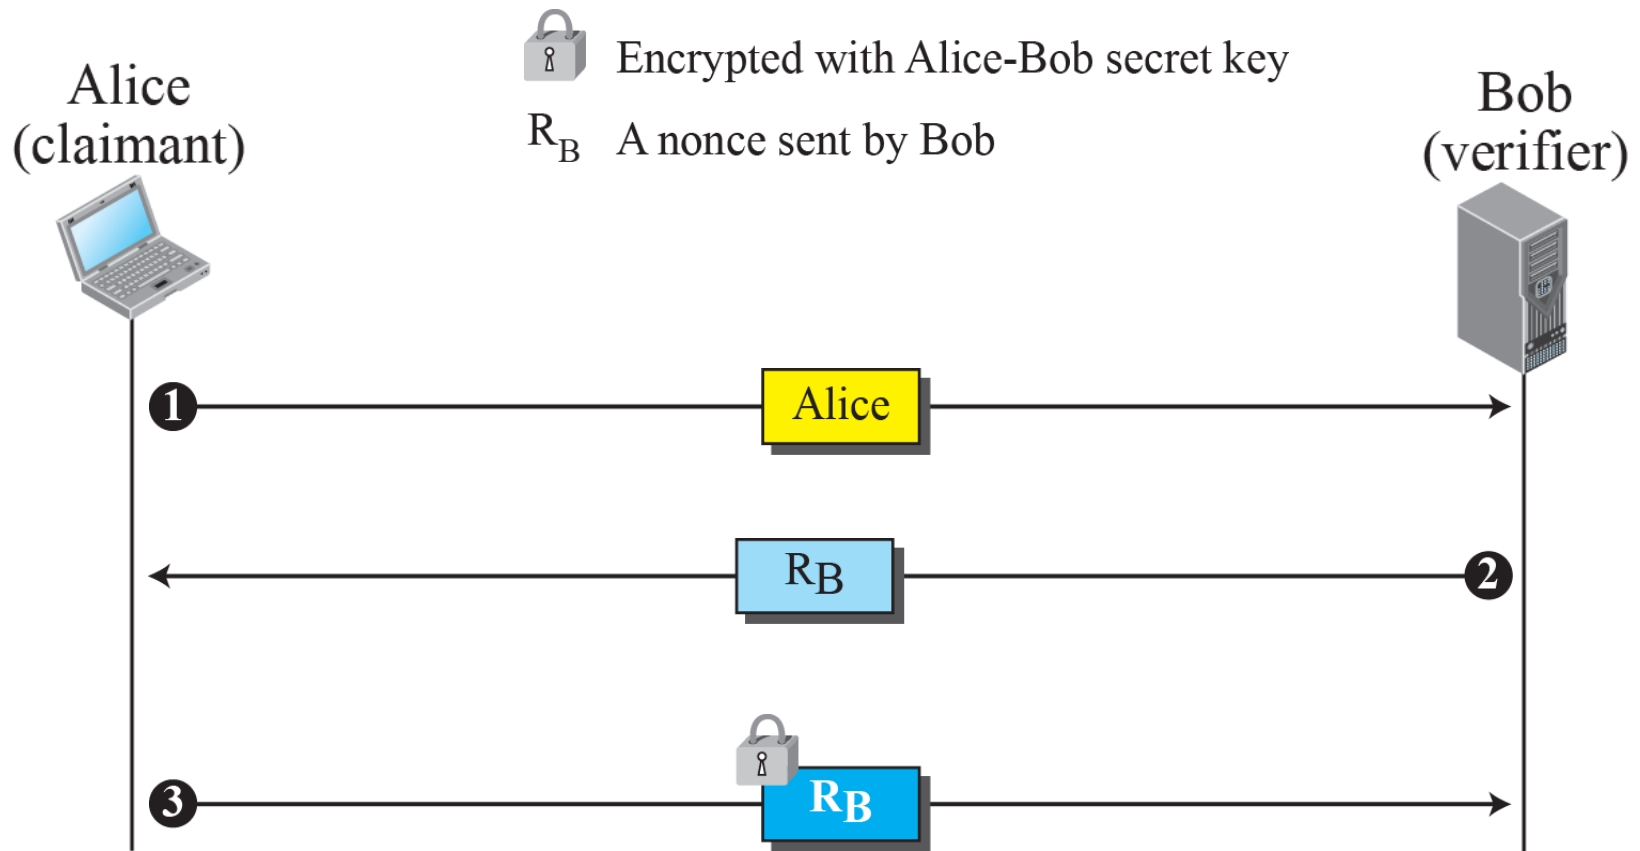

*The RSA signature on the message digest*

# Entity Authentication

---

- Entity authentication is a technique designed to let one party verify the identity of another party.
- An entity can be a person, a process, a client, or a server.
- The entity whose identity needs to be proven is called the claimant; the party that tries to verify the identity of the claimant is called the verifier.

*Unidirectional, symmetric-key authentication*

Alice  
(claimant)

Encrypted with Alice's public key

$R_B$

A nonce sent by Bob

Bob  
(verifier)

1

Alice's private key

*Digital signature, unidirectional authentication*

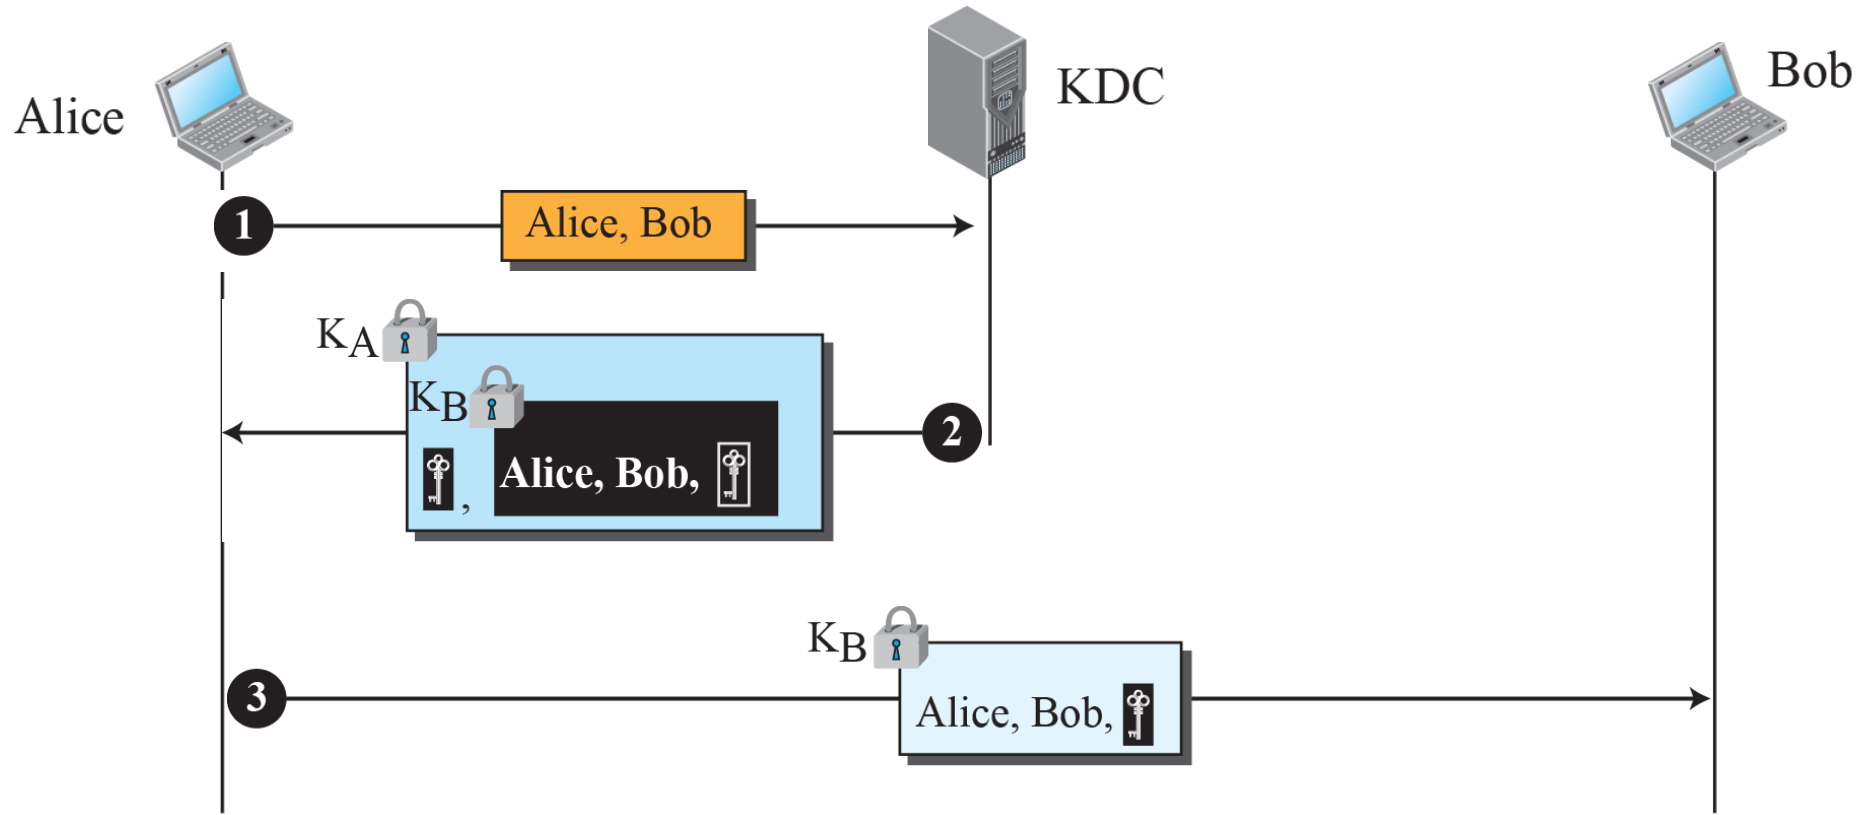

# Key Management

- We discussed symmetric-key and asymmetric-key cryptography in the previous sections.
- However, we have not yet discussed how secret keys in symmetric-key cryptography, and public keys in asymmetric-key cryptography, are distributed and maintained.

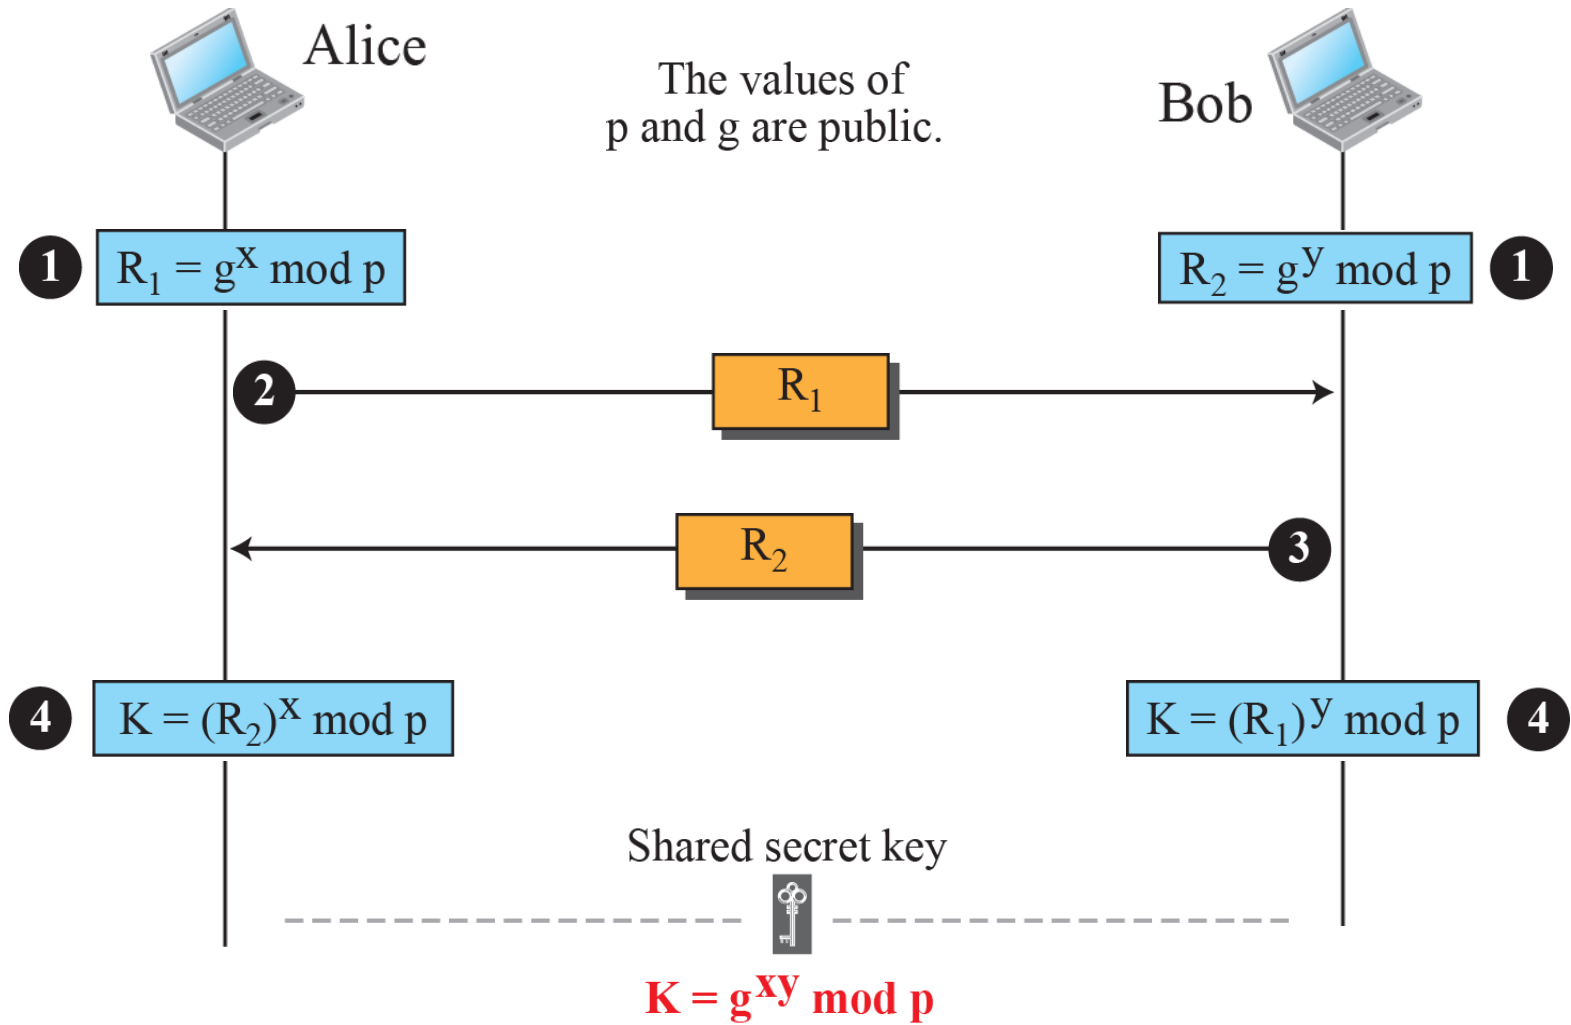

$K_A$   Encrypted with Alice-KDC secret key

 Session key between Alice and Bob

$K_B$   Encrypted with Bob-KDC secret key

*Creating a session key using KDC*

## *Diffie-Hellman method*

# Example

- Let us give a trivial example to make the procedure clear. Our example uses small numbers, but note that in a real situation, the numbers are very large.
- Assume that  $g = 7$  and  $p = 23$ . The steps are as follows:
  1. Alice chooses  $x = 3$  and calculates  $R1 = 7^3 \bmod 23 = 21$ .  
Bob chooses  $y = 6$  and calculates  $R2 = 7^6 \bmod 23 = 4$ .
  2. Alice sends the number 21 to Bob.

# Example (continued)

3. Bob sends the number 4 to Alice.
4. Alice calculates the symmetric key  $K = 4^3 \bmod 23 = 18$ .  
Bob calculates the symmetric key  $K = 21^6 \bmod 23 = 18$ .

## Conclusion:

- The value of  $K$  is the same for both Alice and Bob;  
 $g^{xy} \bmod p = 7^{18} \bmod 23 = 18$ .
